DescriptionField of the Invention

5 The present invention relates to the development of transgenic plants having a modified carbohydrate composition.

Background of the Invention

10 It has long been an objective of the agriculture industry to develop crops having a modified carbohydrate composition, thus providing plants or plant organs more suitable for certain applications. Such modified crops provide plant products having a modified flavor, a higher content of desired saccharides and/or a more desirable texture. These crops may be either consumed directly or used in further processing.

15 In several plant species such as corn (Shannon & Garwood, 1984), pea (Bhattacharyya *et al.*, 1990), potato (Hovenkamp-Hermelink *et al.*, 1987), Arabidopsis (Caspar *et al.*, 1985; Lin *et al.*, 1988a; Lin *et al.*, 1988b) and tobacco (Hanson *et al.*, 1988), mutants with an altered carbohydrate composition have been found. This phenomenon may be attributable to mutations found mainly in enzymes involved in the regulation of the synthesis of starch. Some of these mutants are already used in the food industry, such as sweet corn (Shannon & Garwood, *supra*), which may be directly consumed.

20 Mutants altered in starch metabolism may be obtained via classical techniques such as random screening procedures and breeding. However, these methods are laborious and time consuming processes. Moreover, breeding may give rise to the phenotype that is screened for, but may lead to the loss of other desired characteristics, or the introduction of highly undesired characteristics (such as potatoes having a high alkaloid content). Changing plant characteristics through genetic engineering is a precise and predictable method, the nature of the gene which is spliced into the genome is known and no undesired genes are integrated simultaneously. Finally, modification of a specific characteristic, for instance, the alteration of the level or nature of certain products in the mutant is often difficult or even impossible using classical techniques. As such, genetic modification techniques have opened up new strategies and lead to new products that cannot be obtained by classical techniques.

It would be clearly advantageous to develop sophisticated and predictable methods for obtaining plants having a modified carbohydrate composition, based on genetical engineering techniques.

30 In a U.S. patent 4,801,540, DNA fragments are disclosed encoding an enzyme capable of hydrolyzing poly (1,4- α -D galacturonide) glycan into galacturonic acid. Expression constructs are provided in which the structural gene encoding this enzyme is linked to modified regulatory regions in order to modulate the expression of the enzyme. The purpose of the invention as disclosed in the publication is to decrease expression levels of the polygalacturonase enzyme in order to inhibit the degradation of polygalacturonic acid and thus control fruit ripening.

35 In PCT application WO 89/12386, plants and methods are disclosed in which the carbohydrate content is modified through the expression, *in planta*, of enzymes such as sucrase and levan sucrase. The object of the invention is to increase the concentration of high molecular weight carbohydrate polymers in fruit in order to alter soluble solids and viscosity.

40 European patent application 438,904 describes the modification of plant metabolism (especially in tubers) whereby the level of phosphofructokinase activity is increased, resulting in significantly reduced levels of sucrose and reducing sugars accumulating in the tubers.

East German patent application DD-A-275 704 describes the expression of a microbial glucanase in plants. However, the transformation of barley as proposed in said application and the accompanying regeneration of the barley transformants were not yet established at the filing date of this application and thus are not enabled.

45 PCT application WO 90/12876 describes the regulation of endogenous α -amylase activity in genetically modified potato plants. The disclosure states that a reduction of potato α -amylase activity, and thus a reduction of the degradation of starch to reducing sugars is desirable for the production of potato chips as reducing sugars may be subjected to Maillard reactions during the frying of the potatoes which leads to a detrimental effect on the flavor and texture of the product. On the other hand, the disclosure states that a higher potato α -amylase activity, and thus a higher reducing sugar content is desired if the modified potato tubers are to be used for fermentation for the production of spirits.

Summary of the Invention

55 The present invention provides a method for modifying the carbohydrate composition of a plant or plant organ, said method comprising production of transgenic plants by transformation with a recombinant expression construct comprising two DNA coding sequences, a first one encoding the enzyme amylase and a second one encoding the enzyme glucoamylase.

The present invention also provides DNA expression constructs and vectors for the transformation of plants. The

expression constructs are under the control of regulatory sequences which are capable of directing the expression of the selected polysaccharide modification enzymes. These regulatory enzymes may also include sequences capable of directing the expression of the chosen enzymes at a desired developmental stage of the plant or plant organ and/or tissue specifically.

5 The transgenic plants provided by the present invention find applications as new products with a modified taste, solids content and/or more desirable texture.

 20

Detailed Description of the Preferred Embodiments

25 The present invention provides methods for the production of transgenic plants or plant organs which have a modified polysaccharide composition and overcomes the disadvantages encountered in classical plant breeding techniques by the stable introduction into the plants of DNA sequences encoding an amylase and a glucoamylase which are capable of polysaccharide degradation.

30 It was found unexpectedly that the transformation of tobacco with a bacterial α -amylase gene (lacking a secretory signal sequence) resulted in the accumulation of maltodextrins such as maltose and maltotriose, which is indicative of α -amylase activity. This finding demonstrates that it is possible to modify polysaccharide composition in planta by the introduction and translation of a gene encoding a polysaccharide degrading enzyme.

35 The observed degradation of starch by the introduction of the α -amylase enzyme is very surprising since in plant cells, the entire process of starch synthesis occurs in the specific organelles (chloroplasts, amyloplasts and the like) where starch is stored, whereas the expressed α -amylase is expected to be present in the cytoplasm since no sequences were present to direct the α -amylase to these organelles. Certain starch degrading enzymes are endogenous to the cytoplasm of plant leaf cells. However, their function in the cytoplasm has never been conclusively explained and has never been correlated with the degradation of starch, in planta, because of the compartmental division of the two entities (Caspar et al., 1989; Lin et al., 1988 a,b and c; Okita et al., 1979).
 40

The regulation of the expression of the enzyme indicated above with respect to expression level and spatial (tissue/organ specific) and/or developmental regulation of expression is also a means of obtaining an optimal product. For example, the type and strength of the promoter with respect to the timing and/or location of the expression of the enzyme(s) of interest will provide optimal levels of the enzyme(s) of interest in the desired locus of the transformed plant.

45 Finally, the locus (e.g. cellular compartment or organelle) to which the expressed enzyme may be targeted can be chosen so that an optimal effect, such as better access to the substrate, is obtained.

Variations in expression levels are sometimes observed as a result of varying copy number and/or site of integration of the transforming DNA. This natural variation may be used to select those individual plants from the pool of transgenic plants which have the desired characteristics in terms of sweetness, texture and the like. These individual plants can be used for multiplication and/or breeding with other varieties.
 50

Combinations of the above measures may also be used to obtain the desired effect. Methods of obtaining optimal products may be determined by the skilled artisan using the teaching found below.

According to the present invention, the amylase is encoded by a DNA sequence which is of microbial origin. If necessary, the coding and/or regulatory sequences may be modified to achieve cytoplasmic or organellar expression, tissue specificity or expression at a desired maturity stage of the plant or plant organ. Furthermore, codons may be modified to improve expression of the gene in the selected plant hosts.
 55

Enzymes of interest capable of use in conjunction with the present invention include:

a) starch degrading enzymes such as 1) α -amylases (EC 3.2.1.1); 2) oxo-1,4- α -D glucanases such as amyloglucosidases (EC 3.2.1.3), β -amylase (EC 3.2.1.2), α -glucosidases (EC 3.2.1.20), and other exo-amylases; and 3) starch debranching enzymes, such as isoamylase (EC 3.2.1.68) and the like.

5 Also the glucoamylase is preferably encoded by a DNA sequence of microbial origin.

The source from which DNA sequences encoding the enzymes mentioned above may be obtained is not relevant, provided the enzyme is active in the environment in which the enzyme is expressed or in which the expressed enzyme is targeted.

10 The enzymes mentioned above may be expressed constitutively in the transgenic plants during all stages of development. Depending on the use of the plant or plant organs, the enzymes may be expressed in a stage-specific manner, for instance during tuber formation or fruit development. Furthermore, depending on the use, the enzymes may be expressed tissue-specifically, for instance in plant organs such as fruit, tubers, leaves or seeds.

15 Plant polysaccharides, as defined within the context of the present invention are intended to consist of polyhydroxy aldehydes or ketones, consisting of more than six covalently-linked monosaccharides, which are normally found in plants prior to the action of the enzyme or enzymes of interest according to the present invention. Such polysaccharides are typically polymers of D-arabinose, D-fructose, D- and L-galactose, D-glucose, and D-xylose and mannose.

Saccharide subunits, the desired end-products of the present invention, are defined as saccharides, having a shorter chain length than the original polysaccharide, including monosaccharides, which are obtained via the action of one or more enzymes of interest on the plant polysaccharides.

20 Plants capable of being used in conjunction with the present invention include, but are not limited to crops producing edible flowers such as cauliflower (*Brassica oleracea*) artichoke (*Cynara scolymus*), fruits such as apple (*Malus*, e.g. *domesticus*), banana (*Musa*, e.g. *acuminata*), berries (such as the currant, *Ribes*, e.g. *rubrum*), cherries (such as the sweet cherry, *Prunus*, e.g. *avium*), cucumber (*Cucumis*, e.g. *sativus*), grape (*Vitis*, e.g. *vinifera*), lemon (*Citrus limon*), melon (*Cucumis melo*), nuts (such as the walnut, *Juglans*, e.g. *regia*; peanut, *Arachis hypogaeae*), orange (*Citrus*, e.g. *maxima*), peach (*Prunus*, e.g. *persica*), pear (*Pyrus*, e.g. *communis*), pepper (*Solanum*, e.g. *capsicum*), plum (*Prunus*, e.g. *domestica*), strawberry (*Fragaria*, e.g. *moschata*), tomato (*Lycopersicon*, e.g. *esculentum*), leafs, such as alfalfa (*Medicago*, e.g. *sativa*), cabbages (such as *Brassica oleracea*), endive (*Cichoreum*, e.g. *endivia*), leek (*Allium*, e.g. *porrum*), lettuce (*Lactuca*, e.g. *sativa*), spinach (*Spinacia*, e.g. *oleraceae*), tobacco (*Nicotiana*, e.g. *tabacum*), roots, such as arrowroot (*Maranta*, e.g. *arundinacea*), beet (*Beta*, e.g. *vulgaris*), carrot (*Daucus*, e.g. *carota*), cassava (*Manihot*, e.g. *esculenta*), turnip (*Brassica*, e.g. *rapa*), radish (*Raphanus*, e.g. *sativus*), yam (*Dioscorea*, e.g. *esculenta*), sweet potato (*Ipomoea batatas*) and seeds, such as bean (*Phaseolus*, e.g. *vulgaris*), pea (*Pisum*, e.g. *sativum*), soybean (*Glycin*, e.g. *max*), wheat (*Triticum*, e.g. *aestivum*), barley (*Hordeum*, e.g. *vulgare*), corn (*Zea*, e.g. *mays*), rice (*Oryza*, e.g. *sativa*), tubers, such as kohlrabi (*Brassica*, e.g. *oleraceae*), potato (*Solanum*, e.g. *tuberosum*), and the like.

35 The choice of the plant species is determined by the intended use of the plant or parts thereof and the amenability of the plant species to transformation.

The expression of recombinant genes in plants involves such details as transcription of the gene by plant polymerases, translation of mRNA, etc., which are known to persons skilled in the art of recombinant DNA techniques. Only details relevant for the proper understanding of this invention are discussed below.

40 Regulatory sequences which are known or are found to cause expression of a gene encoding an enzyme of interest in *planta* may be used in the present invention. The choice of the regulatory sequences used depends on the target crop and/or target organ of interest. Such regulatory sequences may be obtained from plants or plant viruses, or may be chemically synthesized. Such regulatory sequences are promoters active in directing transcription in plants, either constitutively or developmental stage- and/or tissue-specifically, depending on the use of the plant or parts thereof. These promoters include, but are not limited to promoters showing constitutive expression, such as the 35S promoter of Cauliflower Mosaic Virus (CaMV) (Guilley *et al.*, 1982), those for leaf-specific expression, such as the promoter of the ribulose biphosphate carboxylase small subunit gene (Coruzzi *et al.*, 1984), those for root-specific expression, such as the promoter from the glutamine synthase gene (Tingey *et al.*, 1987), those for seed-specific expression, such as the cruciferin A promoter from *Brassica napus* (Ryan *et al.*, 1989), those for tuber-specific expression, such as the class-I patatin promoter from potato (Rocha-Sosa *et al.*, 1989; Wenzler *et al.*, 1989) or those for fruit-specific expression, such as the polygalacturonase (PG) promoter from tomato (Bird *et al.*, 1988).

Other regulatory sequences such as terminator sequences and polyadenylation signals include any such sequence functioning as such in plants, the choice of which is within the level of the skilled artisan. An example of such sequences is the 3' flanking region of the nopaline synthase (nos) gene of *Agrobacterium tumefaciens* (Bevan, 1984).

55 The regulatory sequences may also include enhancer sequences, such as found in the 35S promoter of CaMV, and mRNA stabilizing sequences such as the leader sequence of Alfalfa Mosaic Virus (AIMV) RNA4 (Brederode *et al.*, 1980) or any other sequences functioning in a like manner.

In one embodiment of the present invention, if simple expression of an enzyme of interest into the cytoplasm of the plant cell should be desired, the expressed enzyme should not contain a secretory signal peptide or any other

targeting sequence.

In another embodiment of the present invention, the DNA construct encoding a selected enzyme of interest according to the present invention may optionally be provided with leader sequences capable of targeting the expressed enzyme to a predetermined locus in order to have better access of the enzyme to its substrate. Targeting sequences which may be operably coupled to the enzyme of interest in order to achieve this function have been described in the literature (Smeekens *et al.*, 1990; van den Broeck *et al.*, 1985; Schreier *et al.*, 1985). For example, to obtain expression in chloroplasts and mitochondria, the expressed enzyme should contain a specific so-called transit peptide for import into these organelles (Smeekens *et al.*, 1990). If the activity of the enzyme is desired in the vacuoles, a secretory signal sequence must be present, as well as a specific targeting sequence that directs the enzyme to these vacuoles (Tague *et al.*, 1988). This may also lead to the targeting of the enzyme to seeds.

All parts of the relevant DNA constructs (promoters, regulatory-, stabilizing-, targeting- or termination sequences) of the present invention may be modified, if desired, to affect their control characteristics using methods known to those skilled in the art.

Several techniques are available for the introduction of the expression construct containing a DNA sequence encoding an enzyme of interest into the target plants. Such techniques include but are not limited to transformation of protoplasts using the calcium/polyethylene glycol method, electroporation and microinjection or (coated) particle bombardment (Potrykus, 1990).

In addition to these so-called direct DNA transformation methods, transformation systems involving vectors are widely available, such as viral vectors (e.g. from the Cauliflower Mosaic Virus (CaMV), Fraley *et al.*, 1986) and bacterial vectors (e.g. from the genus *Agrobacterium*) (Potrykus, 1990). After selection and/or screening, the protoplasts, cells or plant parts that have been transformed can be regenerated into whole plants, using methods known in the art (Horsch, *et al.*, 1985). The choice of the transformation and/or regeneration techniques is not critical for this invention.

For dicots, an embodiment of the present invention employs the principle of the binary vector system (Hoekema *et al.*, 1983; Schilperoort *et al.*, 1984) in which *Agrobacterium* strains are used which contain a *vir* plasmid with the virulence genes and a compatible plasmid containing the gene construct to be transferred. This vector can replicate in both *E. coli* and in *Agrobacterium*, and is derived from the binary vector Bin19 (Bevan, 1984) which is altered in details that are not relevant for this invention. The binary vectors as used in this example contain between the left- and right-border sequences of the T-DNA, an identical NPTII-gene coding for kanamycin resistance (Bevan, 1984) and a multiple cloning site to clone in the required gene constructs.

The transformation and regeneration of monocotyledonous crops is not a standard procedure. However, recent scientific progress shows that in principle monocots are amenable to transformation and that fertile transgenic plants can be regenerated from transformed cells. The development of reproducible tissue culture systems for these crops, together with the powerful methods for introduction of genetic material into plant cells has facilitated transformation. Presently the methods of choice for transformation of monocots are microprojectile bombardment of explants or suspension cells, and direct DNA uptake or electroporation of protoplasts. For example, transgenic rice plants have been successfully obtained using the bacterial *hph* gene, encoding hygromycin resistance, as a selection marker. The gene was introduced by electroporation (Shimamoto *et al.*, 1989). Transgenic maize plants have been obtained by introducing the *bar* gene from *Streptomyces hygroscopicus*, which encodes phosphinothricin acetyltransferase (an enzyme which inactivates the herbicide phosphinothricin), into embryogenic cells of a maize suspension culture by microprojectile bombardment (Gordon-Kamm *et al.*, 1990). The introduction of genetic material into aleurone protoplasts of other monocot crops such as wheat and barley has been reported (Lee *et al.*, 1989). The stable transformation of wheat cell suspension cultures via microprojectile bombardment has recently been described (Vasil *et al.*, 1991). Wheat plants have been regenerated from embryogenic suspension culture by selecting only the aged compact and nodular embryogenic callus tissues for the establishment of the embryogenic suspension cultures (Vasil *et al.*, 1990). The combination of regeneration techniques with transformation systems for these crops enables the application of the present invention to monocots. These methods may also be applied for the transformation and regeneration of dicots.

If desired, a number of methods may be used to obtain transgenic plants in which more than one enzyme of interest is expressed. These include but are not limited to:

- a. Cross-fertilization of transgenic plants each expressing a different enzyme of interest.
- b. Plant transformation with a DNA fragment or plasmid that contains multiple genes, each encoding an enzyme of interest, each containing its own necessary regulatory sequences.
- c. Plant transformation with different DNA fragments or plasmids simultaneously, each containing a gene for an enzyme of interest, using the necessary regulatory sequences.
- d. Successive transformations of plants, each time using a DNA fragment or plasmid encoding a different enzyme of interest under the control of the necessary regulatory sequences.
- e. A combination of the methods mentioned above.

The choice of the above methods is not critical with respect to the objective of this invention.

In one embodiment of the present invention, an α -amylase is constitutively expressed intracellularly in tobacco and tomato plants, resulting in the degradation of starch in these plants to lower molecular weight saccharides. A genomic DNA fragment encoding mature α -amylase from Bacillus licheniformis, i.e. encoding the α -amylase without the signal peptide sequence, is placed under the control of the CaMV 35S promoter and enhancer sequences. The mRNA stabilizing leader sequence of RNA4 from AIMV is included, as well as the terminator and polyadenylation signal sequences of the nopaline synthase (nos) gene of Agrobacterium tumefaciens. The construct is thereafter subcloned into a binary vector such as pMOG23 (deposited at the Centraal Bureau voor Schimmelcultures, Baarn, the Netherlands on January 29, 1990 under accession number CBS 102.90). This vector is introduced into Agrobacterium tumefaciens which contains a disabled Ti-plasmid. Bacterial cells containing this construct are co-cultivated with tissues from the target plants, and transformed plant cells are selected on nutrient media containing antibiotics and induced to regenerate into differentiated plants on such media. The resulting plants contain the stably integrated gene and express the α -amylase intracellularly.

The α -amylase enzyme activity of the transgenic plants may be tested with direct enzyme assays using colorimetric techniques or gel assays. The assay of choice is not critical to the present invention. The protein is detectable on Western blots with antibodies raised against α -amylase from Bacillus licheniformis.

The plants may be qualitatively assayed for starch content either by staining for starch with iodine. Plants may be quantitatively assayed for the presence of starch degradation products by using techniques as NMR and HPLC. Other methods may also be used. The choice of the method is not critical to the present invention.

In another preferred embodiment, both an α -amylase and a glucoamylase are expressed in potatoes. The enzymes are expressed only in the tubers of the plants. The result is the degradation of starch in tubers by both enzymes to lower molecular weight saccharides. A genomic DNA fragment encoding mature α -amylase from Bacillus licheniformis and a cDNA fragment encoding mature glucoamylase from Aspergillus niger are each placed under the control of the tuber-specific promoter from a class-I patatin gene from potato. Both constructs also include the terminator and polyadenylation signal sequences of the nopaline synthase (nos) gene of Agrobacterium tumefaciens. Both constructs are thereafter subcloned together into the binary vector pMOG23. This vector is introduced into Agrobacterium tumefaciens, which contains a disabled Ti plasmid. Bacterial cells containing this construct are cocultivated with tissues from potato plants and transformed plant cells are selected on nutrient media containing antibiotics, and induced to regenerate into differentiated plants on such media. The resulting plants contain the stably integrated genes. Both α -amylase and glucoamylase are expressed only in the tubers of the transformed potatoes. Both enzymes are expressed intracellularly.

The α -amylase and glucoamylase enzyme activities in the transgenic tubers can be tested with various assays. For example, glucoamylase activity may be determined by an assay measuring p-nitrophenol released from p-nitrophenol- α -D-glucopyranoside by the glucoamylase. Alpha-amylase activity may be measured as described above and in the examples provided below. The presence of both enzymes may be demonstrated by immunoblotting, for example. The choice of assays is not relevant to the present invention.

The transgenic potato tubers may be assayed for their carbohydrate composition by using techniques for the detection of sugars such as HPLC and NMR. Other methods may also be used. The choice of the method is not critical to the present invention.

Transgenic plants or plant organs (such as flowers, fruits, leaves, roots, tubers) having a higher content of polysaccharide degradation products and consequently a modified flavor and/or a desired texture, may be used as a new product either as such or in a form obtained after non-fermentative processing which retains the distinctive qualities resulting from the modification of the plant saccharides. Examples of such uses are the production of baby foods, juices, sauces, pastes, concentrates, sweeteners, jams, jellies, syrups, and animal feeds. Grains having an altered carbohydrate composition may be used in the productions of baked products, for example, which have a modified taste. Tobaccos having an altered carbohydrate composition exhibit a modified taste and aroma.

Alternatively, the polysaccharide degradation products may be extracted from the plant or plant organs and used as such, for instance as a sweetener, or in various processes.

The following examples are provided so as to give those of ordinary skill in the art a complete disclosure and description of how to make and use the invention and are not intended to limit the scope of what the inventors regard as their invention. Efforts have been made to ensure accuracy with respect to numbers used (e.g., amounts, temperature, pH, etc.) but some experimental errors and deviation should be accounted for. Unless indicated otherwise, temperature is in degrees Centigrade and pressure is at or near atmospheric.

Example 1Construction of the binary vector pMOG23.

5 The binary vector pMOG23 (deposited at the Centraal Bureau voor Schimmelcultures, Baarn, The Netherlands, on January 29, 1990, under accession number CBS 102.90; shown in Figure 1) is a derivative of vector Bin19 (Bevan, 1984). First, the positions of the left border (LB) and the right border (RB) were interchanged with reference to the neomycin phosphotransferase gene II (NPTII gene). Secondly, the orientation of the NPTII gene was reversed giving transcription in the direction of LB. Finally, the polylinker of Bin19 was replaced by a polylinker having the following
 10 restriction enzyme recognition sites: EcoRI, KpnI, SmaI, BamHI, XbaI, SacI, XhoI, and HindIII.

Example 2Cloning of the α -amylase gene of *Bacillus licheniformis*

15

All transformations in this example were performed in E. coli strain DH5 α .

a. Tailoring of the α -amylase gene of *Bacillus licheniformis*

20

The α -amylase gene (Figure 2) from *Bacillus licheniformis* is present in the *Bacillus* vector pPROM54, which is described in European Patent Application 224,294, the disclosure of which is hereby incorporated by reference. The plasmid pPROM54 has been deposited at the Centraal Bureau voor Schimmelcultures, Baarn, The Netherlands on November 5, 1985, under accession number CBS 696.85.

25

The plasmid pPROM54 was digested with XbaI and BclI. The XbaI/BclI fragment was cloned in plasmid pUC18 digested with XbaI and BamHI, resulting in plasmid pMOG318. A Sall/BamHI fragment was synthesized with pMOG318 as a template with PCR technology, creating the BamHI site by use of a mismatch primer (the position of the created BamHI site is indicated in Figure 2). The Sall/BamHI PCR fragment was cloned in plasmid pIC-19R (Marsh *et al.*, 1984) digested with Sall and BamHI, resulting in plasmid pMOG319. The Sall fragment from pMOG318 (the second Sall site is present in pUC18), containing the 5' end of the α -amylase gene, was cloned in pMOG319 digested with Sall. This
 30 resulted in plasmid pMOG320 which contains the entire α -amylase gene.

b. Construction of vector pMOG18.

35

The expression cassette of pROK1 (Baulcombe *et al.*, 1986) was cloned as an EcoRI/HindIII fragment into pUC18. This cassette contains the 800 bp Cauliflower Mosaic Virus (CaMV) 35S promoter fragment on an EcoRI/BamHI fragment and the nopaline synthase (nos) transcription terminator of *Agrobacterium tumefaciens* on a BamHI/HindIII fragment. The promoter fragment consists of the sequence from -800 to +1 (both inclusive) of the CaMV promoter. Position +1 is the transcription initiation site (Guilley *et al.*, 1982). The sequence upstream of the NcoI site at position -512 was deleted and this site was changed into an EcoRI Site. This was achieved by cutting the expression cassette present
 40 in pUC18 with NcoI, filling in the single-stranded ends with Klenow polymerase and ligation of an EcoRI linker.

45

The resulting plasmid was cut with EcoRI, resulting in the deletion of the EcoRI fragment carrying the sequences of the CaMV 35S promoter upstream of the original NcoI site. The BamHI/HindIII fragment, containing the nos terminator was replaced by a synthetic DNA fragment (Oligonucleotide duplex A, Figure 3) containing the leader sequence of RNA4 of Alfalfa Mosaic Virus (AIMV) (Brederode *et al.*, 1980). This was done by cleavage with BamHI, followed by cleavage with HindIII and ligation of the synthetic DNA fragment. The BamHI site and three upstream nucleotides were deleted by site-directed mutagenesis.

In the resulting plasmid, the BamHI/HindIII fragment containing the nos terminator was reintroduced. The gene encoding beta-glucuronidase (originating from plasmid pRAJ 275; Jefferson, 1987) was ligated in as an NcoI/BamHI fragment, resulting in plasmid pMOG14.

50

It is known that duplication of the sequence between -343 and -90 increases the activity of the CaMV 35S promoter (Kay *et al.*, 1987). To obtain a promoter fragment with a double, so-called enhancer sequence, the enhancer fragment from plasmid pMOG14 was isolated as an AccI/EcoRI fragment and subsequently blunt-ended with Klenow polymerase. The thus-obtained fragment was introduced in pMOG14 cut with EcoRI and blunt-ended, such that the border between the blunt-ended EcoRI and AccI sites generated a new EcoRI site. The resulting plasmid pMOG18 contains
 55 the 35S CaMV promoter with a double enhancer sequence, the leader sequence of RNA4 from AIMV and the nos terminator in an expression cassette still present as an EcoRI/HindIII fragment.

c. Cloning of the α -amylase gene from *Bacillus licheniformis* in the binary vector.

Plasmid pMOG320 was digested with HgaI and BamHI. The HgaI/BamHI fragment was cloned together with the synthetic oligonucleotide duplex B (Figure 3) into pMOG18 digested with NcoI and BamHI, resulting in plasmid pMOG322. The β -glucuronidase gene was thus replaced by the coding sequence for the mature α -amylase of *Bacillus licheniformis* preceded by the ATG triplet encoding the methionine translation initiation codon. Plasmid pMOG18 contains the 35S promoter and enhancer of Cauliflower mosaic virus (CaMV), the nopal synthase (nos) terminator from *Agrobacterium tumefaciens* and the RNA4 leader sequence of Alfalfa mosaic virus (AIMV). The resulting construct does not contain coding information for a signal peptide. The entire construct was spliced out with EcoRI and HindIII and transferred into the binary vector pMOG23 digested with EcoRI and HindIII. The resulting plasmid has been designated pMOG228 (Figure 4).

The chimeric α -amylase gene on the binary plasmid pMOG228 was mobilized, in a triparental mating with the *E. coli* strain HB101 containing plasmid pRK2013 (Ditta *et al.*, 1980), into *Agrobacterium* strain LBA4404, which contains a plasmid having the virulence genes necessary for T-DNA transfer to the plant (Hoekema *et al.*, 1983).

Example 3

Transformation of tobacco

Tobacco (*Nicotiana tabacum* cv. Petit Havanna SR 1) was transformed by co-cultivation of plant leaf disks (Horsch *et al.*, 1985) with *Agrobacterium tumefaciens*, containing the binary vector pMOG228 with the α -amylase gene. Transgenic plants were selected on kanamycin resistance. The transgenic plants were assayed for activity of the enzyme of interest. Plants expressing the α -amylase gene were analyzed more thoroughly and used in further experiments.

Leaf discs of about 5 x 5 mm were cut from leaves of axenically grown plants of *Nicotiana tabacum* cv. Petit Havanna SR1. The discs were floated for 20 minutes in MS-medium (Murashige & Skoog, 1962) containing 30 g/L sucrose with 1% (v/v) of a culture of *Agrobacterium tumefaciens* LBA4404(pMOG228) (10^9 cells/ml). Subsequently, the discs were briefly dried on filter paper and transferred to plates containing solid medium consisting of MS-medium, containing 30 g/L sucrose, 7 g/L agar, 1 mg/L kinetin and 0.03 mg/L naphthyl acetic acid (NAA). Two days later, the discs were transferred to plates containing the same medium plus 500 mg/L carbenicillin. After one week, the discs were again transferred to plates containing the same medium, this time with about 50 mg/L kanamycin to select for transgenic shoots. Discs were transferred to fresh plates with three week intervals. Developing shoots were excised and transferred to pots containing solid medium consisting of MS-medium, containing 30 g/L sucrose, 100 mg/L kanamycin and 100 mg/L cefotaxime for root development. After roots have developed, the plants were transferred to the soil. The plants were tested for expression of the gene of interest.

Example 4

Alpha-amylase expression in transgenic tobacco plants

Alpha-amylase activity was determined by the method described by Saito (1973) at 56 °C. Units are defined in this case as the amount of enzyme giving a reduction of the absorbance at 690 nm by 10% in 10 minutes. Specific activity for the *Bacillus licheniformis* α -amylase was 8.7×10^5 U/mg protein. The tip of one of the top leaves (about 100 mg) was cut off and homogenized in 100 μ l α -amylase assay buffer (Saito, 1973). The homogenate was spun down for 10 minutes in an Eppendorf centrifuge. The supernatant was collected and assayed for protein and α -amylase content. Control plants had levels of activity at or below the detection limit.

In the 62 transgenic plants obtained, the measured expression levels, as determined by the method of Saito (1973) varied between 0 and 3.29 U/ μ g protein. Based on the specific activity of the enzyme, these levels corresponded to 0 - 0.38 % of the total amount of soluble protein. The average was 0.11 % of the total amount of soluble protein. The protein was clearly present intracellularly, since no significant amount of α -amylase activity was detected in the extracellular fluid that was isolated by vacuum filtration of the leaves with buffer, followed by collection of the fluid by centrifugation (Sijmons *et al.*, 1990). These results were confirmed with immunological detection of the *Bacillus licheniformis* α -amylase on Western blots, which demonstrated that the protein is indeed the desired α -amylase. Further confirmation was obtained by running extracts and extracellular fluid on polyacrylamide-SDS gels. After electrophoresis, the gels were incubated in 0.04 M Tris/HCl pH 7.4 for 3 hours with 6 changes of buffer to renature the enzymes. The gels were overlaid with 0.25% potato Lintner starch, 0.75% agar in 0.05 M Tris/HCl pH 7.4 containing 1 mM CaCl_2 , incubated overnight at 37 °C and subsequently stained with 1mM I_2 /0.5 M KI in water. Alpha-amylase activity was detected as a clear zone in the overlay (Lacks & Springhorn, 1980). In the transgenic plants, an α -amylase was detected having an apparent molecular weight of about 55,000 kDa, the same as that of the *Bacillus licheniformis* α -

amylase.
Tobacco plants expressing α-amylase were pale light green (chlorotic) and somewhat retarded in growth as compared to control plants.

5 Example 5

Carbohydrate analysis of transgenic tobacco plants

10 Qualitatively the starch content in transgenic tobacco leaves, collected at roughly the half-way point of the photoperiod, was determined by destaining the leaves overnight by shaking in 96% ethanol, followed by staining for starch with 5.7 mM I₂ and 43.3 mM KI in 0.2 N HCl. Leaves containing starch stained black-blue, while leaves lacking starch stained brownish-yellow (Caspar et al., 1985).

15 Approximately 2.5 g portions of leaf material (stored in deep-freeze) obtained from control and transformed (good α-amylase expressors) plants were homogenized in 10 ml water at 4 °C with an ultra-turrax. Microscopic inspection revealed that no intact cells remained. After removal of the cell fragments by centrifugation, the glucose oligomer content in the green-colored supernatant was determined. The filtered samples were analyzed via HPLC on an Aminex HPX-42A column (300 mm x 7.8 mm, 85 °C) using water as the eluent. The presence of maltose and maltotriose were detected in the samples of the transformed plants and not in the control (untransformed) plants. The results are shown in Table 1, below.

20

Table 1

Saccharides extracted from tobacco leaves and analyzed on an Aminex HPX-42A-HPLC column		
Preparation	Saccharide	mg Saccharide/g wet material
Control	Maltotriose	undetectable
	Maltose	undetectable
Transgenic	Maltotriose	0.34
	Maltose	1.73

25

30

Example 6

Cloning of the α-amylase gene of Bacillus licheniformis in a tuber-specific expression construct

35

All transformations in E. coli in this example were performed in strain DH5α.
To construct an expression cassette for tuber-specific expression, the promoter from a class-I patatin gene of potato (Solanum tuberosum cv. Bintje) is synthesized using PCR technology with isolated genomic DNA (Mettler, 1987) as a template. Class-I patatin genes show tuber-specific expression in potato. Both the coding and flanking sequences of several members of the patatin multigene family have been determined (Rocha-Sosa et al., 1989; Bevan et al., 1986; Mignery et al., 1988). Chimeric genes have been reported containing 5' flanking regions of a class-I patatin gene fused to β-glucuronidase, giving rise to tuber-specific expression of β-glucuronidase (Wenzler et al., 1989).

40

Two oligonucleotides corresponding to the sequence of the pAT21 and B33 genes (Mignery et al., 1989; Bevan et al., 1986), are synthesized, allowing the amplification of the class-I patatin 5' flanking region as a HindIII/NcoI fragment:

45

5' ATTAAAGCTTATGTTGCCATATAGAGTAGT 3'
5' GTAGGATCCATGGTGCAAATGTTCAAAGTGT 3'

50

The oligonucleotides are designed to contain suitable restriction sites (HindIII and NcoI) at their termini to allow assembly of the expression cassette after digestion of the fragments with the restriction enzymes. A fragment of about 1.3 kb containing a functional class-I patatin promoter fragment was synthesized. After addition of EcoRI synthetic linkers by ligation, the fragment was cloned in pUC18 linearized with EcoRI, resulting in plasmid pMOG546. In a three-way ligation, the HindIII/NcoI-fragment of plasmid pMOG546, together with the NcoI/HindIII fragment of plasmid pMOG322 (see Example 2, encoding mature α-amylase of Bacillus licheniformis preceded by an ATG translation initiation codon and followed by the nos terminator from Agrobacterium tumefaciens) were ligated into the binary vector

55

pMOG23 cut with HindIII, resulting in the binary plasmid pMOG450 (see Figure 5).

Example 7

5 Transformation of tomato

Tomato (Lycopersicon esculentum cv. Moneymaker) was transformed with the Agrobacterium strain LBA4404 (pMOG228). The basic culture medium consisted of MS-medium (Murashige & Skoog, 1962), supplemented with 30 g/L sucrose, B5 vitamins (Gamborg, 1970), 2 mg/L zeatin riboside and 0.1 mg/L indole acetic (IAA). The media were solidified where necessary with 0.7 g/L Daichin agar.

Cotyledons of six day old, axenically grown seedlings were cut on both ends and pre-incubated for 24 hours on solid medium with a feeder of a 10 day old Petunia cell suspension. The cotyledons were subsequently co-cultivated for 20 hours with a log-phase culture of Agrobacterium tumefaciens strain LBA4404 (pMOG228) which was washed with MS-medium. The cotyledons were dried briefly on sterile filter paper and placed on solid medium with a feeder layer of a 10 day old Petunia cell suspension. After 48 hours, the cotyledons were transferred to plates containing the same medium without the feeder layer and with 200 mg/L cefotaxim and 100 mg/L vancomycin. Five days after co-cultivation, the cotyledons were transferred to the same medium plus 100 mg/L kanamycin. The cotyledons were transferred to fresh plates every three weeks.

Shoots were excised and placed on rooting medium (MS-medium supplemented with 10 g/L sucrose, 100 mg/L cefotaxim and 50 mg/L vancomycin). After rooting, the plants were transferred to the soil and subsequently tested for α -amylase expression.

Example 8

25 Expression of α -amylase from Bacillus licheniformis in tomato and carbohydrate analysis of the transgenic fruit

Transgenic tomato plants obtained from the transformation with the constitutive expression construct pMOG228 did not show phenotypic effects. Leaves of the transgenic tomato plants grown for three weeks in soil were assayed for α -amylase activity as described in Example 4. Expression levels of α -amylase in the plants analyzed varied between 0 and 1.2 U/ μ g soluble protein. The presence of the enzyme was confirmed with Western blotting using antibodies raised against Bacillus licheniformis α -amylase.

The starch content in leaves obtained from plants grown for 3 weeks in soil and collected half-way through the photoperiod was determined as described in Example 5. Transgenic plants expressing α -amylase contained demonstrably less starch in their leaves than control plants.

Example 9

Cloning of a cDNA encoding mature glucoamylase from Aspergillus niger

40 All transformations in E.coli in this example were performed in strain DH5 α .

a. Isolation of poly A⁺ RNA from Aspergillus niger

45 About 1×10^8 spores of Aspergillus niger strain DS 2975 (deposited at the Centraal Bureau voor Schimmelcultures on August 10, 1988, under number CBS 513.88) are inoculated in 100 ml pre-culture medium containing (per liter): 1 g KH₂PO₄; 30 g maltose; 5 g yeast-extract; 10 g casein-hydrolysate; 0.5 g MgSO₄·7H₂O and 3 g Tween 80. The pH is adjusted to 5.5.

After growing overnight at 34 °C in a rotary shaker, 1 ml of the growing culture is inoculated in a 100 ml main-culture containing (per liter): 2 g KH₂PO₄; 70 g malto-dextrin (Maldex MDO₃, Amylum); 12.5 g yeast-extract; 25 g casein-hydrolysate; 2 g K₂SO₄; 0.5 g MgSO₄·7H₂O; 0.03 g ZnCl₂; 0.02 g CaCl₂; 0.05 g MnSO₄·4 H₂O and FeSO₄. The pH is adjusted to 5.6. The mycelium is grown for 140 hours and harvested. 0.5 g of dry mycelium is frozen with liquid nitrogen and ground. The material is subsequently homogenized with an Ultra turrax (full speed, 1 minute) at 0°C in 10 ml 3 M LiCl, 6 M Urea and maintained overnight at 4°C as described by Auffray and Rougeon (1980). Total cellular RNA is obtained after centrifugation at 16,000 g and dissolved in 3 ml 10 mM Tris-HCl (pH 7.4), 0.5% SDS and extracting twice with phenol:chloroform:isoamylalcohol (50:48:2). The RNA is precipitated with ethanol and redissolved in 1 ml 10 mM Tris-HCl (pH 7.4), 0.5% SDS. For poly A⁺ selection, the total RNA sample is heated for 5 minutes at 65°C, adjusted to 0.5 M NaCl and subsequently applied to an oligo(dT)-cellulose column. After several washes with an solution containing 10 mM Tris pH 7.0, 0.5% SDS and 0.1 mM NaCl, the poly A⁺ RNA is collected by elution with

10 mM Tris pH 7.0 and 0.5% SDS.

b. Preparation and cloning of a cDNA encoding glucoamylase

5 To synthesize the first strand of the cDNA, 5 µg of poly A⁺ RNA, isolated according to Example 11a, is dissolved in 16.5 µl H₂O and the following components are added: 2.5 µl RNasin (30 U/µl), 10 µl of a buffer containing 50 mM Tris, 6 mM MgCl₂ and 40 mM KCl, 2 µl 1 M KCl, 5 µl 0.1 M DTT, 0.5 µl oligo(dT)₁₂₋₁₈ (2.5 mg/ml), 5 µl 8 mM dNTP-mix, 5 µl BSA (1 mg/ml) and 2.5 µl Moloney MLV reverse transcriptase (200 U/µl). The mixture is incubated for 30 minutes at 37° C and the reaction is stopped by adding 10 µl 0.2 M EDTA and 50 µl H₂O. An extraction is performed using 110 µl chloroform and following centrifugation for 5 minutes, the aqueous layer is collected and 110 µl 5 M NH₄Ac and 440 µl absolute ethanol (temperature: -20°C) are added. Precipitation is performed in a dry ice/ethanol solution for 30 minutes. Following centrifugation for 10 minutes at 0°C, the cDNA/mRNA pellet is washed with 70% ice-cold ethanol. The pellet is dried and dissolved in 20 µl of H₂O.

15 Isolation of a cDNA encoding glucoamylase is performed with the Polymerase Chain Reaction. Two oligonucleotides are synthesized, based on the nucleotide sequence of glucoamylase G1 cDNA published by Boel *et al.* (1984).

20 Oligo 1 : 5' CTTCCACCATGCGACCTTGGATTC 3'
Oligo 2 : 5' AGCTCGAGCTCACC GCCAGGTGTC 3'

25 With these two oligonucleotides, the region encoding the mature enzyme, i.e. without secretory signal peptide and pro-peptide, preceded by a translation initiation ATG codon (underlined) and flanked by suitable cloning sites is amplified. The obtained DNA is digested with NcoI and SstI. Together with the SstI/HindIII-fragment of p35SGUSINT (Vancanneyt *et al.*, 1990) containing the terminator transcript fragment of the CaMV 35S, the NcoI/SstI fragment is cloned in a three-way ligation into pMOG18 (see Example 2), which is digested with NcoI and HindIII, resulting in plasmid pMOG567.

30 The PstI/SstI-fragment of pMOG567 is subsequently cloned in pIC20H (Marsh *et al.*, 1984), digested with PstI and SstI. In the resulting plasmid, the PstI/HindIII-fragment is replaced by the corresponding amyloglucosidase cDNA-fragment, resulting in pMOG568. The sequence of the HindIII/SstI fragment is compared to the sequence published by Boel *et al.* (1984). The PstI/SstI-fragment of pMOG568 is ligated to the PstI/StyI-fragment of the amyloglucosidase cDNA, and the resulting fragment is cloned in a three-way ligation, together with a synthetic adaptor:

35 5' CATGGCGAC 3'
3' CGCTGGAAC 5'

into pMOG567 digested with NcoI and SstI, resulting in plasmid pMOG569 which encodes mature amyloglucosidase under control of the CaMV 35S promoter and terminator.

Example 10

Cloning of both α-amylase from Bacillus licheniformis and glucoamylase from Aspergillus niger

45 All transformations in this example are performed in *E. coli* strain DH5α.

The HindIII/NcoI class-I patatin promoter fragment (see Example 6) from plasmid pMOG546 is cloned, together with the NcoI/HindIII fragment of plasmid pMOG567 encoding mature amyloglucosidase from *Aspergillus niger* and the CaMV 35S terminator fragment (see Example 11), into pIC19R (Marsh *et al.*, 1984) linearized with HindIII, resulting in plasmid pMOG440.

50 Plasmid pMOG450 (see Example 6) is digested with HindIII. The HindIII fragment, containing the class-I patatin promoter, the DNA fragment encoding mature α-amylase from *Bacillus licheniformis* and the nos terminator from *Agrobacterium tumefaciens*, is cloned in the binary vector pMOG23 linearized with HindIII. This results in the binary vector pMOG436.

55 Plasmid pMOG440 is digested with EcoRI. The EcoRI fragment, containing the class-I patatin promoter, the cDNA fragment encoding mature glucoamylase from *Aspergillus niger* and the CaMV 35S terminator, is cloned in the binary plasmid pMOG436, linearized with EcoRI. Using restriction enzyme analysis, transformants are screened for the presence of the two expression cassettes in a tandem orientation. The binary vector with the expression cassettes having this orientation, called pMOG437 (Figure 6) is used for transformation experiments.

The chimeric α -amylase gene from *Bacillus licheniformis* and the chimeric glucoamylase gene from *Aspergillus niger*, both under the control of the tuber-specific class-I patatin promoter, as present on the binary plasmid pMOG437, are mobilized in a triparental mating with the *E. coli* strain HB101 containing plasmid pRK2013 (Ditta *et al.*, 1980) into *Agrobacterium* strain LBA4404 which contains a plasmid having the virulence genes necessary for T-DNA transfer to the plant (Hoekema *et al.*, 1983).

Example 11

Transformation of potato

Potato (*Solanum tuberosum* cv. Désirée) was transformed with the *Agrobacterium* strain LBA4404 (pMOG437) as described by Hoekema *et al.* (1989).

The basic culture medium was a MS30R3-medium, consisting of MS-medium (Murashige & Skoog, 1962), supplemented with 30 g/L sucrose and with R3-vitamins (Ooms *et al.*, 1987) and, where indicated, 5 μ M zeatin riboside (ZR) and 0.3 μ M indole acetic acid (IAA). The media were solidified where necessary with 0.7 g/L Daichin agar.

Tubers of *Solanum tuberosum* cv. Désirée were peeled and surface-sterilized for 20 minutes in 0.6% hypochlorite solution containing 0.1% Tween-20. The potatoes were washed thoroughly in large volumes of sterile water for at least 2 hours. Discs of approximately 2 mm thickness were sliced from cylinders of tuber tissue prepared with a corkbore. Discs were incubated for 20 minutes in a suspension consisting of the MS30R3-medium without ZR and IAA, containing between 10^6 - 10^7 bacteria/ml of *Agrobacterium* LBA4404 (pMOG437). The discs were subsequently blotted dry on sterile filter paper and transferred to solid MS30R3-medium with ZR and IAA. Discs were transferred to fresh medium with 100 mg/L cefotaxim and 50 mg/L vancomycin after 2 days. A week later, the discs were again transferred to the same medium but this time 100 mg/L kanamycin was present to select for transgenic shoots. After 4-8 weeks, shoots emerged from the discs at a frequency of 5-10 shoots per 100 discs. Shoots were excised and placed on rooting medium (MS30R3-medium without ZR and IAA, but with 100 mg/L cefotaxim and 100 mg/L kanamycin), and propagated axenically by meristem cuttings and transferred to soil. The plants were allowed to tuberize and were subsequently tested for expression of the genes of interest.

Example 12

Simultaneous tuber-specific expression of both α -amylase (*Bacillus licheniformis*) and glucoamylase (*Aspergillus niger*) in potato and carbohydrate analysis of transgenic tubers

Potato plants are transformed with binary vector pMOG437 as described in Example 7. The plants are assayed for both α -amylase and glucoamylase activity. Alpha-amylase activity is determined as described in Example 4. The presence of glucoamylase is demonstrated by Western blotting, using antibodies raised against *Aspergillus niger* glucoamylase. Plant material (about 50 mg) is homogenized in 100 μ l assay buffer and homogenized. The homogenate is spun for 10 minutes in an Eppendorf centrifuge. The supernatant is tested for α -amylase activity, for the presence of glucoamylase and for protein content. The presence of the enzymes is only detected in the tubers of the transgenic potatoes.

Tubers of transgenic potatoes expressing both enzymes are analyzed for the presence of soluble sugars by HPLC. A higher content of soluble sugars is found in transgenic tubers as compared to control plants.

Claims

1. A method for modifying the carbohydrate composition of a plant or plant organ, said method comprising production of transgenic plants by transformation with a recombinant expression construct comprising two DNA coding sequences, a first one encoding the enzyme amylase and a second one encoding the enzyme glucoamylase.
2. A method according to claim 1, characterized in that said amylase is alpha-amylase.

3. A method according to claim 2, characterized in that said amylase is alpha-amylase from *Bacillus licheniformis*.
4. A method according to any of claims 1-3, characterized in that the glucoamylase originates from *Aspergillus niger*.
5. A method according to any of claims 1-4, wherein said expression construct contains regulatory sequences operably linked to and capable of directing the expression of said DNA coding sequences at a selected maturity stage of the development of the transgene plant or plant organ.
6. A method according to any of claims 1-4, wherein said expression construct contains regulatory sequences operably linked to and capable of directing tissue-specific expression of said DNA coding sequences.
7. A method according to any of claims 1-6, wherein said DNA coding sequences encoding the enzyme are fused to a nucleotide sequence encoding a leader sequence that is operably linked to said enzyme, said leader sequence being capable of targeting the enzyme to a cellular compartment or organelle.
8. A method according to any of claims 1-7, further characterized in that said transgenic plant is selected from the group consisting of tomato, potato, corn, cassava, carrot, lettuce, strawberry and tobacco.
9. A recombinant expression construct which comprises two DNA sequences, a first one encoding an alpha-amylase enzyme and a second one encoding a gluco-amylase enzyme.
10. A construct according to claim 9, characterized in that the alpha-amylase originates from *Bacillus licheniformis*.
11. A construct according to claim 9 or 10, characterized in that the gluco-amylase originates from *Aspergillus niger*.
12. A vector comprising an expression construct according to any of the claims 9-11.
13. A bacterial strain characterized in that said bacterial strain contains a vector according to claim 12.

Patentansprüche

1. Verfahren zur Abänderung der Kohlehydratzusammensetzung einer Pflanze oder eines Pflanzenorgans, welches Verfahren die Herstellung von transgenen Pflanzen durch Transformation mit einem rekombinanten Expressionsconstruct umfasst, wobei letzteres zwei DNA-codierende Sequenzen umfasst, von welchen die erste für das Enzym Amylase und die zweite für das Enzym Glucoamylase codiert.
2. Verfahren nach Anspruch 1, dadurch gekennzeichnet, dass besagte Amylase alpha-Amylase ist.
3. Verfahren nach Anspruch 2, dadurch gekennzeichnet, dass besagte Amylase alpha-Amylase aus *Bacillus licheniformis* ist.
4. Verfahren nach irgendeinem der Ansprüche 1-3, dadurch gekennzeichnet, dass die Glucoamylase aus *Aspergillus niger* stammt.
5. Verfahren nach irgendeinem der Ansprüche 1-4, dadurch gekennzeichnet, dass besagtes Expressionsconstruct Regulationssequenzen enthält, welche mit diesem auf funktionsfähige Art gebunden und zur Steuerung der Expression besagter DNA-codierender Sequenzen bei einem bestimmten Reifestadium der Entwicklung der transgenen Pflanze oder des transgenen Pflanzenorgans befähigt sind.
6. Verfahren nach irgendeinem der Ansprüche 1-4, in welchem besagtes Expressionsconstruct Regulationssequenzen enthält, welche mit diesen auf funktionsfähige Art gebunden und zur Steuerung der gewebespezifischen Expression besagter DNA-codierender Sequenzen befähigt sind.
7. Verfahren nach irgendeinem der Ansprüche 1-6, in welchem besagte DNA-codierende Sequenzen, welche für das Enzym codieren, mit einer Nucleotid-Sequenz fusioniert sind, welche für eine Leader-Sequenz codiert, die an besagtes Enzym auf funktionsfähige Art gebunden ist, und wobei besagte Leader-Sequenz zur Steuerung des Enzyms zu ein Zellenabteil oder zu eine Organelle befähigt ist.

8. Verfahren nach irgendeinem der Ansprüche 1-7, weiterhin dadurch gekennzeichnet, dass besagte transgene Pflanze aus der Gruppe ausgewählt ist, welche aus Tomate, Kartoffel, Mais, Kassawa, Karotte, Lattich, Erdbeere und Tabak besteht.
- 5 9. Rekombinantes Expressionsconstruct, welches zwei DNA-Sequenzen umfasst, von welchen die erste für das Enzym alpha-Amylase und die zweite für das Enzym Glucoamylase codiert.
10. Construct nach Anspruch 9, dadurch gekennzeichnet, dass die alpha-Amylase aus *Bacillus licheniformis* stammt.
- 10 11. Construct nach Anspruch 9 oder 10, dadurch gekennzeichnet, dass die Glucoamylase aus *Aspergillus niger* stammt.
12. Vektor, welcher ein Expressionsconstruct nach irgendeinem der Ansprüche 9-11 umfasst.
- 15 13. Bakterienstamm, dadurch gekennzeichnet, dass besagter Bakterienstamm einen Vektor nach Anspruch 12 enthält.

Revendications

- 20 1. Procédé pour modifier la composition en hydrates de carbone d'une plante ou d'un organe végétal, ledit procédé comprenant la production de plantes transgéniques par transformation avec une construction recombinante d'expression comprenant deux séquences codantes d'ADN, une première codant pour l'enzyme amylase et une deuxième codant pour l'enzyme gluco-amylase.
- 25 2. Procédé selon la revendication 1, caractérisé en ce que ladite amylase est l' α -amylase.
3. Procédé selon la revendication 2, caractérisé en ce que ladite amylase est l' α -amylase de *Bacillus licheniformis*.
- 30 4. Procédé selon l'une quelconque des revendications 1 à 3, caractérisé en ce que la gluco-amylase provient de *Aspergillus niger*.
- 35 5. Procédé selon l'une quelconque des revendications 1 à 4, dans lequel ladite construction d'expression contient des séquences régulatrices liées de façon fonctionnelle auxdites séquences codantes d'ADN à un stade de maturité sélectionné du développement de la plante transgénique ou de l'organe végétale, ou capables de diriger l'expression desdites séquences.
- 40 6. Procédé selon l'une quelconque des revendications 1 à 4, dans lequel ladite construction d'expression contient des séquences régulatrices liées de façon fonctionnelle auxdites séquences d'ADN et capables de diriger une expression à spécificité de tissu desdites séquences.
- 45 7. Procédé selon l'une quelconque des revendications 1 à 6, dans lequel lesdites séquences codantes d'ADN codant pour l'enzyme sont condensées avec une séquence de nucléotides codant pour une séquence de tête qui est liée de façon fonctionnelle à ladite enzyme, ladite séquence de tête étant capable de cibler l'enzyme vers un organelle ou compartiment cellulaire.
- 50 8. Procédé selon l'une quelconque des revendications 1 à 7, caractérisé en outre en ce que ladite plante transgénique est choisie dans l'ensemble constitué par la tomate, la pomme de terre, le maïs, le manioc, la carotte, la laitue, la fraise et le tabac.
- 55 9. Construction recombinante d'expression qui comprend deux séquences d'ADN, une première codant pour une enzyme α -amylase et une deuxième codant pour une enzyme gluco-amylase.
10. Construction selon la revendication 9, caractérisé en ce que l' α -amylase provient de *Bacillus licheniformis*.
11. Construction selon la revendication 9 ou 10, caractérisé en ce que la gluco-amylase provient de *Aspergillus niger*.
12. Vecteur comprenant une construction d'expression selon l'une quelconque des revendications 9 à 11.

13. Souche bactérienne caractérisée en ce que ladite souche bactérienne contient un vecteur selon la revendication 12.
